⌄ Basic Terminologies

⌄ 1. Experiment

- It is basically an activity which I'm trying to do.

> **Let's say I have this mathematical equation**

$a^2 + b^2 + 2ab$

where: a = 3 and b = 4

$3^2 + 4^2 + 2(3)(4)$ = 49

- We are 100% sure that the result of this equation will be 49 only. It cannot be 50 or 48.

This type of experiment is called **Deterministic Experiments** where we can **determine** the exact output, like in this case.

Now, let's see another few more examples:

- Flipping a coin

  - When you flip a coin, there are two possible outcomes: it can land either `heads` or `tails`.

- Rolling a six-sided die

  - When you roll the die, the outcome is uncertain, and the die can land on any of the six faces.

- Cricket Match

  - Suppose there is a match going on between 2 teams, we can't determine the match result.

In all of these above examples, we can notice one common thing.

> **Q. Can we determine the outcome of all these experiments?**

No, because the outcomes are uncertain. These types of experiments are known as **Probabilistic Experiments**.

Let's continue with the experiment of "Rolling a six sided die" and look at the possible results of an experiment.

Experiment: Rolling a die

2. Outcomes

- Suppose we roll a six sided die and we want to know the possible `Outcomes`.

- We know that we could get any digit out of the 6 digits. So, an outcome could be : {1} or {2} or {3} or {4} or {5} or {6}

3. Sample Space

- It is the collection of all the possible outcomes of the experiment.

So the **sample space** for this experiment will be: **{1, 2, 3, 4, 5, 6}**

⌄ 4. Events

We know that sample space for die is {1,2,3,4,5,6}.

If we say,

> **An Even number is rolled / While rolling a die, an even number has occurred**

- Then the possible outcomes will be: `{2, 4, 6}`

This is known as an `Event` .
Any subset of sample space is an event.

- {2, 4, 6} is a subset of sample space.

"**An Even number is rolled**" is an event here and its output is E = {2, 4, 6}, where E denotes an Event.

> **Q1. What are the possible outcomes when a dice is rolled and a number greater than two has occurred?**

- For this Event, outcome will be E = {3, 4, 5, 6}

Here is a graphical representation of a sample space and events

- Here the **sample space** S is represented by a rectangle which is {1, 2, 3, 4, 5, 6}
- **Outcomes** are represented as points within the rectangle which is {1}, {2}, {3}, {4}, {5}, {6}

- **Events** are represented as ovals that enclose the outcomes that compose them.
    - we have two events, $E1$: {2, 4, 6} which is an event for "Even number is rolled"
    - $E2$: {3, 4, 5, 6} which is an event for "A number greater than 2 rolled"

Now let's see few experiments.

⌄ **Experiment 1: Tossing a single coin**

> **Q1. If we toss a single coin then what can be the Possible Outcomes for this experiment?**

- Either we can get **Heads**
- Or we can get **Tails**

Therefore, our outcome becomes: **{H}, {T}**

The **Sample Space** for this experiment will be S **= {H, T}**

> ### Based on this sample space, what possible Events can be defined?

Getting Heads while tossing a coin,

- then our event will be E = {H}

Getting Tails while tossing a coin,

- then our event will be E = {T}

> ### Q2. Suppose the given subset is itself {H,T}. Can we define this as an Event or not?

Yes, It is an event.

- We discussed earlier that any subset of a Sample Space is an Event.

- Also an entire set is a subset of itself so this is a valid event.

> ### Q3. So how can we frame this event?

It is the "**Event of getting Either Heads or Tails**".

> ### Q4. Consider the empty set as the given subset denoted by { }. Is it a valid event?

- We know that, an empty set is a subset of every set. An empty set is therefore a subset of sample space

- It is a valid subset

- So by going with the definition of an Event, we can conclude that this is a valid event.

This can be represented as the "**Event of getting neither Heads nor Tails**".

> ### Q5. Is it possible if we toss a coin and get nothing?

No, it is not possible.

- Therefore, we will have an **Empty set** here

- As we know an empty set is a subset of sample space, therefore it is an Event.

But, the probability of getting a Null Set (No outcome) is Zero.

As it is not possible to toss the coin and don't get any output. we will either gets a head or a tail.

> **Q6. How many subsets can be formed from the sample space?**

There is one formula to find the number of subsets : 2^N

- where N = number of elements in sample space

For the above experiment, number of elements in the sample sapace is 2 {H,T}, So N = 2

- Therefore the number of subsets will be $2^2 = 4$
- Subsets will be **{ {H}, {T}, {H,T}, { } }**

From this, we can conclude that an empty set is also considered as a valid subset.

Set Operations

Let's recall the experiment "**Rolling a die**" for which the **Sample space** is $\{1, 2, 3, 4, 5, 6\}$

- We can also represent this as a **Universe** or **Universal Set** in context of set operations
- Universal set is the collection of all possible sets

Now let's define some events:

- Mohit bets that he will get an odd number
    - So the outcome of this **Event** will be $A = \{1, 3, 5\}$
- Rakesh bets that he will get either 1, 5 OR 6
    - $B = \{1, 5, 6\}$
- Abhishek bets that he will get an Even number
    - $C = \{2, 4, 6\}$

There are some some questions which can arise

Intersection

> **Q. In which condition, both Mohit and Rakesh will win their bets?**

We want a number which occurs in both of their events

They will win their bets when we get a number 1 or 5 on a die.

- Therefore $\{1, 5\}$ is the possible outcome such that both Mohit and Rakesh will win their bets

This is known as an **Intersection** of two events.

- It is denoted as $A \cap B$

- Intersection means **members belonging to both A AND B**

  - So, $A \cap B$ will consists only of the elements present in both events, which in this case are $\{1, 5\}$

Image source: https://www.desmos.com/calculator/nynlqmtuu2
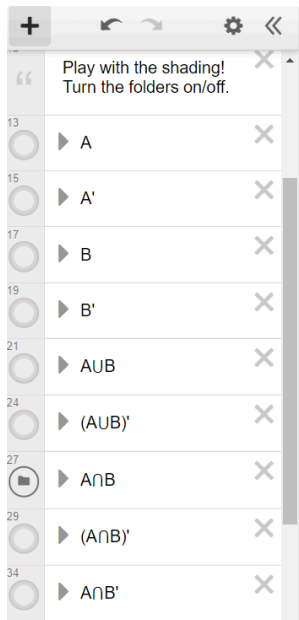

⌄ Union

Now the next question,

### Q. When either Mohit or Rakesh will win their bets?

If we get any number out of 1, 3, 5 or 6

- Possible outcomes of this event: $\{1, 3, 5, 6\}$

This is known as **Union** of Two events A and B

- It is denoted by $A \cup B$

- So, **Union** means **members belonging to either A OR B**
- So, $A \cup B$ will combine their outcomes, which in this case will be $\{1, 3, 5, 6\}$

Complement

> **Q. When will Mohit lose his bet?**

Mohit will lose his bet if the outcome is $\{2, 4, 6\}$

This is known as **complement** of Event A, denoted by A' or A^c

We can define it as the set that contains all the elements except the elements of A, denoted as $A' = U - A$

While Rakesh will lose if the outcome is $\{2, 3, 4\}$

- Hence $B' = \{2, 3, 4\}$

⌄ **Mutually Exclusive Events (Disjoint Events)**
> **Q1. What will be the output of $A \cap C$?**

We will have an empty set $\{\ \}$ which can also be represented by $\emptyset$

Because there are no common elements in Set A and Set C

Or it implies that **both the events can't occur on the same time** means we can't get an **Even number and a Odd number** at the same time on the dice.

- So, when two events cannot occur at the same time or simultaneously then these types of events are known as `Mutually Exclusive Events` or `Disjoint Events`

A and B are mutually exclusive

Exhaustive Events

> **Q. What will be the output of $A \cup B \cup C$?**

Our events are:

- $A = \{1, 3, 5\}, B = \{1, 5, 6\}, C = \{2, 4, 6\}$
  - Therfore $A \cup B \cup C$ = combined elements of Event A, B, C = {1, 2, 3, 4, 5, 6}

This is nothing but the **Sample Space** of our experiment **"Rolling a die"** as these events when combined, giving the all possible outcomes.

- These types of events are known as `Exhaustive Events`

## ∨ Non Mutually Exclusive Events (Joint Events)

Suppose we define one more Events:

- **Event D**: Rolling a number greater than 3 = (4, 5, or 6).

> **Q. Can we say that Events C (getting even) and D are mutually exclusive?**

No, as we can get a number that is both even and greater than 3, which means both **events C and D can occur simultaneously**.

- For instance, if the die shows a 4 or a 6, it fulfills the criteria for both events C and D.
- This type of events are known as `non-mutually exclusive` or `joint events`

A and B are not mutually exclusive

∨ Independent Events

While non-mutually exclusive events allow for overlap, where more than one event can occur, independent events focus on how the occurrence of one event **may or may not affect** the likelihood or outcome of another event

Suppose we have 2 two events:

- **Event A**: Rolling an even number (2, 4, or 6)

- **Event B**: Flipping a coin and getting heads

> **Q. Are these two events Independent or not?**

YES, these events are `independent Events` because

- The outcome of rolling the die (**Event A**) `does not affect the outcome` of flipping the coin (**Event B**), and vice versa.

They are unrelated events that are occurring independently.

And if two events A and B are independent, then the probability of happening of both A and B is:

- $P(A \cap B) = P(A) * P(B)$

In case of Disjoint events, $P(A \cap B)$ **= 0** , as A Intersect B = { }

- **So, if the Events are Independent they cannot be Mutually Exclusive or Disjoint and vice a versa**

In the upcoming lectures, we will see how to derive this formula and also prove this claim.

⌄ How to calculate Probability

Now if I want to calculate the Probability of the particular event let's say event A, then we can calculate using this.

$$Probability = \frac{Outcomes\ in\ set\ A}{Total\ Outcomes\ in\ Entire\ Sample\ Space}$$

Now, let's take a random Experiment whose **outcome** could be **{1} or {2} or {3} or {4} or {5} or {6}**, then the **Sample Space** will be **{1, 2, 3, 4, 5, 6}**

Let's define some events:

1. **$A$$A$ = {2, 4, 6}**

> **Q1. What will be the probability of Event A?**

- By looking into the formula = $\Large\frac{Possible \ oucomes}{Total \ outcomes}$
- Possible outcomes of event A = 3 and total Outcome in sample space = 6

So, $P(A) = $$\Large\frac{3}{6}$$

2. B = {1, 2}

- Similarly Probability of Event B will be $P(B)$ = $\Large\frac{2}{6}$

3. C = {1, 4, 5, 6}

- and Probability of Event C will be $P(C)$ = $\Large\frac{4}{6}$

Addition Rule

> **Q1. What will be the Probability of $P(A∪B)$?**

First we need to find $A \cup B$ which is **{1, 2, 4, 6}**

- So by the formula of probability $P(A∪B)$ will be = $\Large\frac{|A∪B|}{|S|}$ = $\Large\frac{ |\{1, 2, 4, 6\}|}{|\{1, 2, 3, 4, 5, 6\}|}$ = $\Large\frac{4}{6}$

Where, |$A∪B$| = Number of elements(cardinality) of ($A∪B$) set,
and |S| = Number of elements in Sample Space

If we want to represent using venn Diagram:

> **Q2. What will be Probability of $P(A∩B)$?**

$A∩B$$A∩B$ will be **{2}**

- So by the formula of probability $P(A∩B)$$P(A∩B)$ will be = $\Large\frac{ |\{2\}|}{|\{1, 2, 3, 4, 5, 6\}|}$$\Large\frac{ |\{2\}|}{|\{1, 2, 3, 4, 5, 6\}|}$ = $\Large\frac{1}{6}$$\Large\frac{1}{6}$

So by looking into Venn diagram, we observe that AUB means addition of all the elements of **Set A** and **Set B**

- We can also notice in set A we have {2, 4, 6} and in set B we have {1, 2}

- While adding the outcomes of the sets, {2} is occuring twice, which is nothing but $A∩B$$A∩B$, so we have to subtract it once from our addition, as we want unique outcomes only (Since a set can only have distinct elements).

So the formula for $P(A ∪ B)$$P(A ∪ B)$ can we written as:

- **$P(A∪B) = P(A) + P(B) - P(A∩B)$$P(A∪B) = P(A) + P(B) - P(A∩B)$**

This is known as `Addition Rule`. This is for Joint Events

In case of **Disjoint Events**

- the intersection of $A ∩B = \{ \ \}$$A ∩B = \{ \ \}$ so, $P(A∩B) = 0$$P(A∩B) = 0$

  - therefore, **$P(A∪B) = P(A) + P(B)$**

⌄ Experiment 3: Sachin Tendulkar ODI records for India

⌄ Problem Statement:

We have a dataset containing Sachin Tendulkar's ODI cricket career stats, including various performance metrics and the outcomes of matches.

```

```python
df_sachin = pd.read_csv("Sachin_ODI.csv")
```

```python
df_sachin.head()
```

	runs	NotOut	mins	bf	fours	sixes	sr	Inns	Opp	Ground	Date	Win
0	13	0	30	15	3	0	86.66	1	New Zealand	Napier	1995-02-16	Zea
1	37	0	75	51	3	1	72.54	2	South Africa	Hamilton	1995-02-18	S A
2	47	0	65	40	7	0	117.50	2	Australia	Dunedin	1995-02-22	I

Each columns represents different features and each row represents a particular match

```python
# shape of the dataset
df_sachin.shape
```
```
(360, 14)
```

Q1. A match is randomly chosen, what is the probability that India have won that match?

Solution:

Let's calculate this using the formula of probability, we know:

probability = $\Large\frac{Possible \ Outcomes \ in \ an \ event}{Total \ Outcomes\ in \ an \ Entire \ Sample \ Space}$

Here we want the possible outcomes of India winning a match (WON = True)

Entire sample space will be our entire dataset

```
# find the rows where India have won and store into new dataframe
df_won=df_sachin.loc[df_sachin["Won"]==True]
```

```
# calculate the number of True values which is our possible outco
df_won.shape[0]
```

184

```
# We can also look at the length using len()
len(df_won)
```

184

- So, probability

  = $\Large\frac{number \ of \ matches \ won}{total \ number \ of \ matches}$

```
prob_winning=len(df_won)/len(df_sachin)
prob_winning
```

0.5111111111111111

Conclusion: :

If a match is randomly chosen, there is **51%** chance that India have won that match.

Q2. A match is chosen at a random, what is the probability that Sachin has scored a Century in that match?

Solution 2:

Let's solve this using value counts function. First let's count the **number of centuries**, Sachin has scored

```
# using value_counts()

df_sachin["century"].value_counts()
```

```
False    314
True      46
Name: century, dtype: int64
```

Out of 360 matches, Sachin has scored 46 Centuries.

so, probability of Sachin scoring a century will be:

```
46/360
```

```
0.12777777777777777
```

Conclusion:

If you chose a random match, there is **12.77% chance** that Sachin has scored a century in that match

⌄ **Cross Tab:**

Now,

Let's find out how many matches India have won when Sachin has `scored a century` and

How many matches India have won when sachin `didn't score a century`.

> **Q. Can we achieve this task and obtain all these values at once?**

```
df_sachin[["century","Won"]].value_counts()
```

```
century  Won
False    False    160
         True     154
True     True      30
         False     16
dtype: int64
```

⌄ Cross Tab and contingency table

Q. Do you remember pivot table from DAV-1 Libraries module?

- There is a function called `pd.crosstab()` , which accepts parameters **index** and **columns**.

```
pd.crosstab(index=df_sachin["century"],
            columns=df_sachin["Won"],
            margins=True)
```

Won	False	True	All
century			
False	160	154	314
True	16	30	46
All	176	184	360

What we did using `.valuecounts()` at above, `pd.crosstab()` did the same thing but converted the output into nice tabular format

- **Century** is taken as the **index** and **Won** is taken as **columns**
- When we do **Margins = True** we get **All**, both in rows and columns,
  - The values of **All** in a ROW represents the **Total Value** of each columns (False, True, All)
  - The values of **All** in a COLUMN represents the **Total Value** of each rows (False, True, All)

This table is also known as `Contingency Table`

We can calculate probabilities using the contingency table.

⌄ Q3. A match is chosen at a random. What is the probability that Sachin has scored a century in that match and India have won that match?

Solution 3:

```
pd.crosstab(index=df_sachin["century"],
            columns=df_sachin["Won"],
            margins=True)
```

Won	False	True	All
century			
False	160	154	314
True	16	30	46
All	176	184	360

```
# prob of winning and century
# Won -> True, century -> True
```

```
30/360
```

`0.08333333333333333`

Conclusion :

There is **8% chance** that Sachin has scored a century and India have won that match if we choose a random match

This tells us, that **contingency table** is more convenient to calculate probabilities rather than hard coded the every single line

⌄ Conclusion of the Problem statement:

Let's have a look how is Sachin's batting can or cannot impact the winning chances of India

1. Out of the **360** matches that Sachin has played, India have **won 184** matches and Loose 176 matches.

2. So, if we choose any match at a random from Sachin's ODI career, there is a **51%** chance that India have won that match.

3. Now, If we choose a random match from Sachin's ODI career, there is **12.77%** chance that Sachin has scored a century in that match.

4. We know if a random match is choosen, there is 12.77% chance that Sachin has scored a century but

there is **only 8%** chance India have won that match.

- we can conclude that the chances of India, Winning a match is more when Sachin didn't score a century (what an amazing insight)

Finally,

We can conclude that, if we pick a random match where Sachin played, India's win percentage is 51%. There is 12.77% chance of Sachin scoring a century in that match, and there is only 8% chance that in that match Sachin scores a century as well as India have won that match
